

Bisnate (Milano): estate 2002

This field is representative of some of the changes taking place in Italian lodging during the summer of 2002. Immediately noticeable are the more compact, regular laid areas, accompanied by a reduction in the number of isolated tufts. A new feature: the borders are much neater, straighter and more parallel than in preceding years. Note the absence of "island tufts". A new feature: the plants are beginning to be bent all at the same height of the stalk and in the same direction, forming a smooth homogeneous surface. A perfect spiral. More than 30 people observed a multitude of miniscule golden spheres swirling in the air above it. However the presence of these lights was not registered by any of the photos taken: a typical example of what we have termed "selectivity", which seems to characterize crop circles, in which a single event is recorded/seen/heard by some instruments/observers present in a field and not by the others. A new feature: a pile of seeds that have been severed from plants in the laid area by an unknown process with extreme precision and piled up in an area of standing crop several metres away from the plants they were severed from
